A couple features

Personas

Micheal, age 45, living in Portland, is the **single father of two 11-years old twin girls**. He is a **full time hairdresser** and has a very busy schedule, and often gets unexpected appointments. Because of this, he wants to improve his communication with his daughters and his household management. Since he isn't using computers a lot for his work, he possesses only very basic skills in IT, as such he values easy to use applications.

Marina, age 24, living in Hong-Kong, is a **graphic designer for a video game company**. She uses tools such as Clip Studio Paint to draw her textures and blender to build and animate her models, and finds herself at ease with any digital tools. She is an intuitive person who easily figures how websites and applications work. She is aware of agile practices and sees them as a way to improve her communication with her department

Michael has decided to **improve his and his daughters' organization** by making to do lists, where a member of the household and a time slot are assigned to handle each task.

After **having created their to-do tasks** for the upcoming week, he notices that each good to buy in the shopping list is considered an individual task by the application (while the shopping list is a folder grouping the goods).

As this kind of display is too complicated for him, he asks his daughter to **create another display method** for "shopping list" item (a single "shopping list" task with the goods to buy written in its description, still with checkboxes to tick).

→ **The application should have many display options i.e. inserting subtasks in the description of a task**

In the context of her project, **Marina** is asked to **report the progress on the current 3D model she is working on**.

This report - that she will submit as an attached file to the "report" task that is shared with her manager in the to-do app- should mention the progress she has done on her assigned tasks and show a preview of her ongoing work.

However, when **uploading her 3D model's components** to the to-do app, she notices it **does not support all file types**, including .blend files. Therefore, to be able to show her mesh, she **uploads it on a cloud and includes a link to it in the report**.

→ **The application should support attached files and of many types (excluding potentially malicious types).**

Some user stories

As a non-expert in the use of IT and applications, I want a tutorial to appear when I install the app, which will explain to me the most important features of the application at first, and continue showing me the details if I choose to try any of them.

As a daughter in household, I want to have my other family members' favorite goods being automatically written in the next shopping list, so i don't have to ask them each time *

As the artist in my division, I want a comment section under each task, where I can get feedback and eventually likes from my colleagues.

As an artisan, I want crafting tutorials to be recommended to me depending on the tasks that I have entered (and I want either an AI to sort the tutorials or a feedback function so only the best ones get recommended).

As a CEO, I want to use the hierarchy of my company on the to-do app, so the leaders of each division or subdivision can track the progress of their members, and easily communicate with of the group they're in charge of. *

*CORRECTIONS to the pdf submitted on Moodle (which was full of typing mistakes), p2, first line after *Task import/scan/transfer Epic*, and page 3, last user story for the company employees

Features derived from the user stories

04

Description:

The tutorial should appear after the installation of the app, showing the most important features to the user. If the user wants to use more complex features, the tutorial will continue by the moment he tries to use them.

As such, it is a way to find a balance between simplicity and functionality, since the most simple features will be at the foreground, easily accessible to users that seek simplicity, and complex features will still be available for those who seek functionality - but with a little bit of discovery required.

Tutorial

Comment:

A "skip tutorial" option should be available to users who are already familiar with this kind of app.

Description:

A comment section may be used for each task or project, where the user can report eventual issues, leave a note to another user, get feedback ect.

-Task comment section
(+emoji feedback)

Comment:

A quick feedback option, using a "like" or an emoji, is to be considered.

Description: Similarly to the calendar, if the task copier detects the creation of a new task with a name that is similar to a previous one (example: Grocery list // Shopping list. The elements that are common in all files having a name containing these words will get copied to the next one that is created).

Task content transfer

Constraints: Contrarily to the calendar this duplication process should not be automatic and require the user's approval each time it is suggested to be effective (unless if the user manually sets this feature to automatic).

Features derived from the user stories

04

Description: If the title of a task or project corresponds to something recognized by an AI (for example, if the title is "Bake pizza", or "Buy shampoo"), the AI should suggest related content that could help the user completing their task (here for example, a pizza recipe video, or a shampoo recommendation) directly on the app.

Constraints: To avoid giving irrelevant or even annoying suggestions to the user, the AI should only suggest widely reviewed pages (like popular youtube videos or wikiHow tutorials), at least during the first phase after the application launch. Data from the most used suggestions during this phase could then be collected and used to improve the recommendation algorithm. This feature should also be possible to disable manually by the user.

Intelligent tutorial
or product suggestion

Comment:
Product suggestion can also be used as a way to generate revenue to the product owner.

Description: The head of an organization or supervisor of a household may create groups (divisions and subdivisions) for the project and give progress monitoring permissions to the leaders of each division / subdivision.

Constraints: Although leaders should be able to monitor their group's work on the project, any employee with a To Do Space account should have the right to create other projects that are kept private if needed, for privacy reasons.

Account management
inside company:
hierarchy

Comment:
The progress may be monitored in various ways, for example by using percentages/stats, Kanban boards, reports, etc...
